IDENTIFIERS Parent Characteristics

ABSTRACT

This KIDS COUNT report presents statistics highlighting challenges faced by newborns and their parents in major urban areas. Data came from birth certificates. Overall, children living in central cities are far more likely to experience six risks associated with negative child outcomes, and when those six factors are used collectively to determine which children are high risk, 20 percent of children living in central cities are high risk, compared to only 8 percent of those living in suburbs and 14 percent of those living outside metropolitan areas. The report describes key indicators, including: percent of total births to women under age 20; percent of teen births to women who were already mothers; percent of total births to unmarried women; percent of total births to mothers with less than 12 years of education; percent of total births to mothers receiving late or no prenatal care; percent of total births to mothers who smoked during pregnancy; percent low-birthweight babies; percent preterm babies; percent healthy births; and percent of high risk births based on maternal characteristics. City profiles present key indicators, 1997; the number of births by maternal characteristics, 1997; the healthy birth index, 1997; and the risk index based on maternal characteristics, 1997. Two appendixes present cities ranked by indicator, 1997, and states ranked by indicator, 1997. The report also includes definitions and data sources and primary contacts for state KIDS COUNT projects. (SM)

KIDS COUNT, a project of the Annie E.

Casey Foundation, is a national and state-by-state effort to track the status of children in the United States. By providing policymakers and citizens with benchmarks of child well-being, KIDS COUNT seeks to enrich local, state, and national discussions concerning ways to secure better futures for all children. At the national level, the principal activity of the initiative is the publication of the annual *KIDS COUNT Data Book*, which uses the best available data to measure the educational, social, economic, and physical well-being of children. The Foundation also funds a nationwide network of state-level KIDS COUNT projects that provide a more detailed community-by-community picture of the condition of children.

This *KIDS COUNT Special Report* could not be produced and distributed without the help of numerous people. The publication was assembled and produced under the general direction of Dr. William P. O'Hare, KIDS COUNT Coordinator at the Annie E. Casey Foundation, with help from Amy R. Ritualo.

We are enormously appreciative of the work of Stephanie J. Ventura and Sally C. Curtin from the National Center for Health Statistics, who made special tabulations available for this publication. Without their efforts, this report would not have been possible.

We also owe a debt of gratitude to Melissa Long, Richard Wertheimer, and Justin Jager of Child Trends, who organized the data for this publication.

Special thanks are also due Beth Clawson, Beverly Hunter, Scott Rier, and Samuel Shelton of KINETIK Communication Graphics, Inc., who were responsible for the design of the book, and to the staff at podesta.com for providing assistance in the promotion and dissemination of the *Special Report*.

Finally, we would like to thank the state KIDS COUNT projects listed on page 91 for helping us distribute this *Special Report* to national, state, and local leaders across the country.

Permission to copy, disseminate, or otherwise use information from this *Special Report* is granted as long as appropriate acknowledgment is given.

To obtain additional copies of this publication, call 410.223.2890 or write to the Annie E. Casey Foundation, Attn: *KIDS COUNT Special Report*, 701 St. Paul St., Baltimore, MD 21202.

This report is also available on the Internet at www.aecf.org.

The circumstances and conditions under which a baby is born have lifelong implications. A child whose mother receives little or no prenatal care is far more likely to experience chronic health problems than other children whose mothers did receive prenatal care. A woman who smokes or drinks during pregnancy may visit long-term damage on the children she bears. An infant born into a family that is poor faces a considerably greater risk of not reaching his or her full potential.

In this *KIDS COUNT Special Report, The Right Start: Conditions of Babies and Their Families in America's Largest Cities*, we highlight the particular challenges faced by newborns and their parents in the nation's major urban areas. We are especially interested in the implications for the millions of kids born into families living in the toughest neighborhoods of our biggest cities.

The extent of disparity between the "life starts" of some inner-city kids and the rest of our children amounts to an assault on our national confidence in the principle of equal opportunity.

This *KIDS COUNT Special Report* contains no earth-shattering surprises. On one level, it simply records the predictable: A greater percentage of kids born in America's big cities are born with high risk factors than is true for America as a whole or for more affluent suburbs in particular.

While this may not merit banner headlines, the facts here deserve more attention than they have so far received. For one thing, the extent of disparity between the "life starts" of some inner-city kids and the rest of our children amounts to an assault on our national confidence in the principle of equal opportunity. Pregnant women in the nation's capital, for example, are three times more likely to go without timely prenatal care than the national average. Twice as many of the babies born in Baltimore are a lower birthweight than is normal for the rest of the country. Births in Detroit are one and one-half times more likely to be premature than births elsewhere in America. An infant in St. Louis is more than twice as likely to be born to an unmarried mother than are other American children.

Even within the universe of big cities, the disparities in birth circumstances are startling. A baby born in Houston is four times more likely to have a mom who

didn't finish high school than is a newborn in Seattle. And a pregnant woman in Columbus is three times more likely to go without timely prenatal care than her counterpart in Nashville.

The data and comparisons presented in this *Special Report* do not lend themselves to simple and certain answers, but they do pose crucial questions. Foremost among these is the following: What variables or factors are most helpful in explaining the patterns we find in the birth data presented in this *KIDS COUNT Special Report*?

Part of the answer lies in the broad dynamics of race and class. America's large cities are home to a disproportionate share of the country's low-income and minority populations. The disadvantages of poverty and discrimination lie behind many of the negative urban indicators presented in the pages that follow.

That said, however, there are some other correlations that may be equally instructive in interpreting data,

The Casey Foundation has increasingly centered its work on the proposition that children do best when their families do well, and families do better when they live in supportive neighborhoods.

Framing problems, and advancing solutions. For the past several years, the Casey Foundation has increasingly centered its work on the proposition that children do best when their families do well, and families do better when they live in supportive neighborhoods. Stated negatively, kids fare the worst when families are weak, and families are weakest in those communities that lack access to economic opportunity, positive social networks, and quality public education and service systems.

Neighborhoods like these—neighborhoods that are tough places for families to form and flourish—can be found throughout American cities, counties, and suburbs. But they are far more common in our central urban areas and more common in some cities than in others. In our analysis, it is the prevalence of these isolated, disinvested neighborhoods in major metropolitan areas that explains why so many cities produce such alarming statistics on family risk factors and such terrible numbers on birth measures.

This place-based, family-centered theory has led us to conclude that improving prospects for the kids most at risk in the United States means nothing less than working to rebuild family-supporting opportunities, initiatives, and values in the very neighborhoods where families are now faring the worst. Over the next decade, the Casey Foundation will work with local partners on precisely this approach in many of the cities that recorded the most disturbing numbers in this report.

Whether or not our interpretation of these numbers is persuasive or our approach to the underlying problems is sound, one fact remains beyond debate: The disparity in opportunity represented by the statistics in this *Special Report* is unacceptable. It is a threat to our cities, our economy, our future, and our basic democratic values. Somehow, we must find a way to ensure that more of our children get a decent and more equal start on the promise of a productive and fulfilling American life.

18

19

Urban centers were selected as the focus of this *KIDS COUNT Special Report* because evidence clearly shows that outcomes for children in large cities are generally more problematic than those for children living in other areas of the country. Figure 1 indicates that children living in central cities are far more likely to experience each of six risks associated with negative child outcomes. Moreover, when these six factors were used collectively to determine which children were high-risk kids (those with four or more of these risk factors), analysis showed that “20 percent of kids living in central cities are in the high-risk category, compared to only 8 percent of those living in suburbs and 14 percent of those living outside metro areas.”¹

Since data on births provide one of the few types of systematic measures reflecting child well-being that are available consistently for all large cities, we relied on data from

Summary

8

birth certificates to construct this *KIDS COUNT Special Report*. Moreover, recent research on brain development has underscored the importance of stimulation and human interaction experienced in the earliest years of childhood. Conditions at birth often reflect the forces that will shape a young person's life. In 1997 there were 754,685 births in the 50 largest U.S. cities that are the major focus of this report. This represents almost one-fifth of all births in the United States.

The data from birth certificates provided on the pages that follow reflect several kinds of risks faced by newborns. Measures such as lack of timely prenatal care and percent of mothers who smoked during pregnancy reflect social conditions prior to birth that can affect the health of an infant. Other measures reported here, such as birthweight and gestation period, reflect health status at the time of birth. Finally, we included three characteristics of the mother (marital status, age, and education) that are likely to be related to the conditions a newborn may experience early in life.

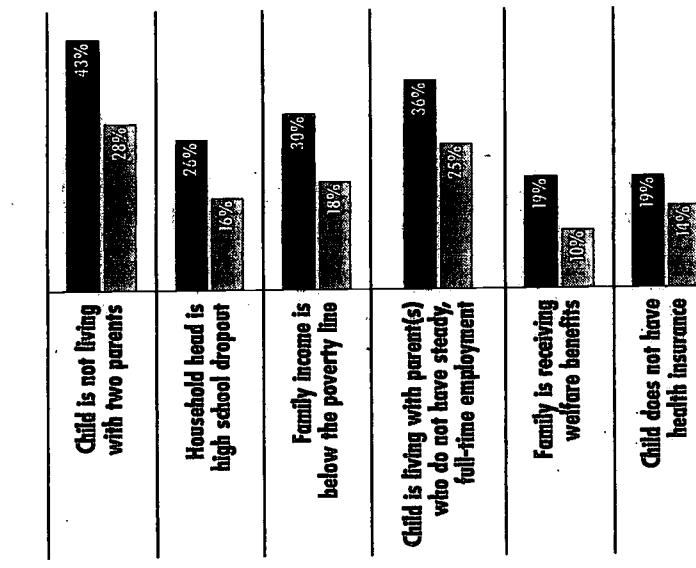

The measures show enormous variation across the 50 cities, but it is clear that collectively, birth outcomes in the largest cities are not as good as those elsewhere.

FIGURE 1
Characteristics of Children Inside and Outside Central Cities

Central cities is a term used by the Census Bureau to identify those large cities located at the core of metropolitan areas. Collectively, these figures represent about 500 cities nationwide.

Outside central cities includes suburban as well as rural areas.

The figures shown here represent about 90 percent of American children. The location (inside central cities/outside central cities) of some respondents was not revealed in the data file released by the Census Bureau in order to protect their confidentiality.

TABLE 1
Key Indicators of Births in Large Cities and Nationwide: 1997

Indicator	Top 50-City Average	The Nation
Percent of total births to women under age 20	14.9	12.7
Percent of teen births to women who were already mothers	23.8	21.6
Percent of total births to unmarried women	43.0	32.4
Percent of total births to mothers with less than 12 years of education	27.7	22.1
Percent of total births to mothers receiving late or no prenatal care	5.4	3.9
Percent of total births to mothers who smoked during pregnancy*	11.2	13.2
Percent low-birthweight babies (less than 5.5 pounds)	8.8	7.5
Percent preterm babies (less than 37 completed weeks of gestation)	12.6	11.4
Percent healthy births*	61.6	66.8
Percent of births that were high risk based on maternal characteristics	8.6	6.6

SOURCE: The figures for the Top 50-City Average and the national figure for Parent Healthy Births were calculated by Child Trends based on data provided by the National Center for Health Statistics. Other figures come directly from the National Center for Health Statistics.

*Not all cities are included in the 50-city average, and not all states are included in the national figure for this indicator.

Table 1 shows how birth outcomes in the 50 largest cities compare to those nationwide. We decided to use the simple 50-city averages, rather than weighted averages, in Table 1 to be consistent with the data presented for each city in the next section of this report.

In nearly every case (the exception is smoking during pregnancy), the outcomes in large cities are worse than those for the rest of the nation. Additionally, the city-wide numbers presented here often mask important variations within a city. For example, studies in Baltimore and Cleveland show that negative birth outcomes such as low birthweight and infant mortality are concentrated in neighborhoods with high poverty and/or low per capita income.² Studies suggest that negative birth outcomes are part of a constellation of measures that point toward neighborhoods with concentrated poverty and diminished opportunity.

While these measures can hardly capture the full range of forces shaping the lives of newborns, the indicators used in this *Special Report* reflect several important dimensions of a newborn's life. Moreover, these indicators are consistently measured across all of the cities, thus permitting legitimate comparisons. Since many of the conditions related to a birth are linked to later developmental problems, the data illuminate future prospects for children in these cities.

Summary

The 55 cities that are the focus of this *Special Report* include the 50 largest cities as of 1997 (according to population estimates from the U.S. Census Bureau) plus 5 cities that are not in the top 50, but are part of the Casey Foundation's 22-city *Making Connections* initiative. More information about the *Making Connections* initiative is provided at the end of this section, along with a list of the cities in the initiative. Of the 22 cities, 16 are among the 50 largest cities in the country, 5 more are shown here, and 1 (Camden, New Jersey) could not be included here because the population is below 100,000, which is the cutoff point that the National Center for Health Statistics (NCHS) has set for providing data in the detail shown in this report. The 5 *Making Connections* cities that are not in the top 50 are identified as such on the following pages.

developed a method for estimating the standard errors for measures such as those presented here.³

In addition to outcome measures for each city, we also include some raw data, such as population and number of births, as well as number of births by selected maternal characteristics. We did not include the number of births for Asian and Pacific Islander Americans or American Indians because the number of births in these groups was very small in most cities. Data for all of the states are provided in Appendix 2.

In the following pages we describe each of the measures in more detail, explain why each measure was selected as an indicator of well-being, and discuss how the measure is related to broad, long-term outcomes.

The key indicators of birth outcomes used here are all taken from NCHS and reflect the official data for each indicator. While these measures are not derived from samples, many are based on relatively small numbers of births and therefore may exhibit a degree of random fluctuation from year to year. Small differences among cities may reflect random fluctuations rather than "real" distinctions in the well-being of children. Therefore, we urge readers to focus on those differences that are relatively large. For those who are interested, NCHS has

developed a method for estimating the standard errors for measures such as those presented here.³

In addition to outcome measures for each city, we also include some raw data, such as population and number of births, as well as number of births by selected maternal characteristics. We did not include the number of births for Asian and Pacific Islander Americans or American Indians because the number of births in these groups was very small in most cities. Data for all of the states are provided in Appendix 2.

In the following pages we describe each of the measures in more detail, explain why each measure was selected as an indicator of well-being, and discuss how the measure is related to broad, long-term outcomes.

PERCENT OF TOTAL BIRTHS TO WOMEN UNDER AGE 20

Teenage childbearing is problematic because it often diminishes the opportunities of both the child and the young mother. Births to women under age 20 are particularly troublesome because most of these mothers are unmarried, and a large segment have not completed high school. For example, only 22 percent of teenagers who gave birth in 1997 were married, and only 37 percent had completed 12 or more years of education.

Children born to teenage mothers are less likely to obtain the emotional and financial resources they need to develop into independent, productive, well-adjusted adults.

If a large share of the births in a city are occurring to teenagers, it means that a significant number of children are starting life with a parent who is unlikely to have the resources needed to provide for a child. Most teenage mothers are not settled in a job or career, and many young fathers are not able to help. Data from the Census Bureau indicate that only 3 percent of mothers ages 15 to 17 received child-support payments in 1995.⁴ Data from the March 1998 Current Population Survey show that only 56 percent of males ages 16 to 19 had any earned income in 1997 and that the average annual income for those who worked was slightly less than \$5,000.

Children born to teenage mothers are less likely to obtain the emotional and financial resources they need to develop into independent, productive, well-adjusted adults. Thus, babies born to teens reflect a group of children who will have to overcome high odds to thrive. It is important to note that the Percent of Total Births to Women Under Age 20 is influenced by the fertility

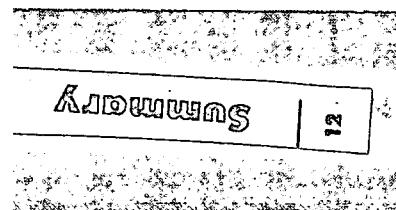

of older women (above age 20) as well as teens. For more information on this point, see Definitions and Data Sources.

While 12.7 percent of all births in the country occurred to women under age 20 in 1997, the average was 14.9 percent in the 50 largest cities (see Table 1). Seattle had the lowest Percent of Total Births to Women Under Age 20 (6.3 percent), while Baltimore had the highest (22.8 percent). Nationally, the share of births to women under age 20 stayed nearly constant during the 1990s (12.8 percent in 1990 compared to 12.7 percent in 1997; see Table 2).

For more information on this topic, readers are referred to a KIDS COUNT Special Report titled *When Teens Have Sex: Issues and Trends*, which provides a wealth of information related to teen childbearing and sexual activity on a state-by-state basis.⁵

PERCENT OF TEEN BIRTHS TO WOMEN WHO WERE ALREADY MOTHERS

Most teen mothers are ill-equipped to provide for one child, and a second one severely compounds that challenge. Therefore, children born to a teenage mother who already has one or more children are unlikely to receive the kinds of support that children need to

thrive. Moreover, a high rate of repeat teen births signals a problem with pregnancy prevention programs and offers a key opportunity for policy or program intervention.

While 21.6 percent of all births to teens in the country were repeat births in 1997, the average was 23.8 percent for teen births in the 50 largest cities (see Table 1). Percent of Teen Births to Women Who Were Already Mothers ranged from a low of 14.8 percent in San Francisco to a high of 31.0 percent in the District of Columbia and Tulsa. National data suggest that this problem has diminished during the 1990s. A recent NCHS report showed that the birth rate for second births to teenagers was 21 percent lower in 1996 than in 1991.⁶ The percent of teen births that were repeat births decreased from 25.1 percent in 1990 to 21.6 percent in 1997 (see Table 2).

PERCENT OF TOTAL BIRTHS TO UNMARRIED WOMEN
Research shows that children growing up with a single mother⁷ are more likely to drop out of school, to give birth out of wedlock, to divorce or separate, and to be dependent on welfare.⁸ Numerous recent studies document the importance of fathers in the lives of their children. "Children develop best when they are pro-

vided with the opportunity to have warm, intimate, continuous, and enduring relationships with both their fathers and their mothers."⁹ Even if a marriage fails, children born into a married-couple family have advantages over those born to unmarried women. The poverty rate for single-parent families headed by a never-married mother is 55 percent, compared to 35 percent for families headed by a divorced or separated mother. Also, in 1997 the Infant Mortality Rate of children born to an unmarried mother was almost twice that of children born to married mothers (10.5 compared to 5.6 deaths per 1,000 live births).¹⁰

The marital status of parents at the time of birth reflects the likelihood of a child receiving a child-support award. Data from 1995 indicate that among never-married single parents, only 44 percent had a child-support award in place, compared to 76 percent of divorced single parents. But it should be noted that many custodial parents with child-support awards in place never receive money they are due. Only 21 percent of never-married single parents actually received child-support payments in 1995, compared to 51 percent of divorced single parents.¹¹

While 32.4 percent of all births in the country occurred to unmarried women in 1997, the average was

43.0 percent in the 50 largest cities (see Table 1). The Percent of Total Births to Unmarried Women ranged from a low of 24.5 percent in Honolulu to a high of 71.6 percent in Detroit. National data suggest that this problem increased during the early 1990s, but was stable from 1994 to 1997. The Percent of Total Births to Unmarried Women increased from 28.0 percent in 1990 to 32.6 percent in 1994, and was 32.4 percent in 1997 (see Table 2).

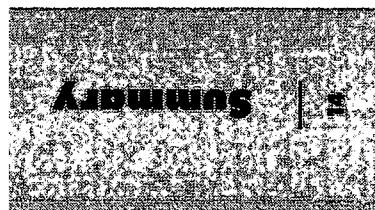

PERCENT OF TOTAL BIRTHS TO MOTHERS WITH LESS THAN 12 YEARS OF EDUCATION

Research has consistently shown that the education level of a child's mother is a good predictor of many child outcomes.¹¹ Consequently, children born to women who have not graduated from high school face tough odds. The Infant Mortality Rate for births to women with less than 12 years of education was 9.2 deaths per 1,000 live births in 1997, compared to 6.3 for women with at least a high school education.¹² Women who do not get a good formal education are often less likely to provide the kind of educational and intellectual stimulation that their children need. Moreover, people with less education are less likely to be effective advocates for their children when they enter school or encounter problems with other institutions or public systems.

Nationwide in 1997, 22.1 percent of births occurred to women with less than 12 years of education, but within the 50 largest cities, the average was 27.7 percent (see Table 1). The Percent of Total Births to Mothers With Less Than 12 Years of Education ranged from a low of 9.5 percent in Honolulu to a high of 47.1 percent in Los Angeles. Nationally, the Percent of Total Births to Mothers With Less Than 12 Years of Education declined slightly during the 1990s, going from 23.5 percent in 1990 to 22.1 percent in 1997 (see Table 2).

PERCENT OF TOTAL BIRTHS TO MOTHERS RECEIVING LATE OR NO PRENATAL CARE

Mothers who receive timely prenatal care are less likely to have babies with health problems. Failure to obtain early prenatal care may reflect a mother's indifference to her pregnancy, or it may reflect a lack of available care. Either situation is cause for concern. A woman who makes sure that she gets proper prenatal care is also likely to make sure that she does other things to protect her newborn. Failure to find timely prenatal care may also reflect the fact that a woman is in a precarious situation where many other kinds of resources are simply not available. Since the availability of health insurance is related to obtaining good prenatal care, women in large cities are at a disadvantage. Among women of childbearing age (15 to 44), those living in

central cities are much less likely than those living elsewhere to have health insurance.

If a large segment of births in a city are to mothers who do not receive good prenatal care, it should provide a signal that health providers must become more aggressive in their outreach and public information campaigns to educate and inform mothers about the importance of prenatal care.

Nationwide, 3.9 percent of all births in 1997 occurred to mothers who did not receive timely prenatal care, compared to an average of 5.4 percent in the 50 largest cities (see Table 1). Among the 50 largest cities, the share of births occurring to women who lacked timely prenatal care ranged from a low of 2.5 percent in Charlotte, to a high of 12.3 percent in the District of Columbia. Nationwide, there is good news on this front. The share of mothers lacking timely prenatal care fell from 6.1 percent in 1990 to 3.9 percent in 1997 (see Table 2).

PERCENT OF TOTAL BIRTHS TO MOTHERS WHO SMOKED DURING PREGNANCY
 Babies born to mothers who smoked during pregnancy are more likely to have health problems. According to a recent report¹³ from the National Center for Health

TABLE 2
Changes in U.S. Birth Outcomes: 1990 and 1997

Indicator	1990	1997
Percent of total births to women under age 20	12.8	12.7
Percent of teen births to women who were already mothers	25.1	21.6
Percent of total births to unmarried women	28.0	32.4
Percent of total births to mothers with less than 12 years of education	23.5	22.1
Percent of total births to mothers receiving late or no prenatal care	6.1	3.9
Percent of total births to mothers who smoked during pregnancy	18.4	13.2
Percent low-birthweight babies (less than 5.5 pounds)	70	75

SOURCES: National Center for Health Statistics, National Vital Statistics Reports, Vol. 47, Nos. 10, 12, and 18.

Smoking during pregnancy may be symptomatic of other conditions that reflect an unhealthy approach to pregnancy and childbearing.

the 41 cities that collect these data, the rates ranged from a low of 2.6 percent in New Orleans to a high of 23.6 percent in Pittsburgh. Nationally, the share of babies born to mothers who smoked during pregnancy has been declining, dropping from 18.4 percent in 1990 to 13.2 percent in 1997 (see Table 2).

PERCENT LOW-BIRTHWEIGHT BABIES (LESS THAN 5.5 POUNDS)

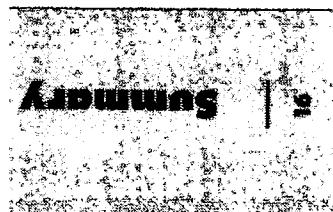

While most American children get off to a healthy start, babies weighing less than 2,500 grams (about 5.5 pounds) at birth have a high probability of experiencing developmental problems. Therefore, the Percent Low-Birthweight Babies reflects a group of children who are more likely to have health problems as they move through the growth stages.

Nationally, 291,154 babies were born weighing less than 5.5 pounds in 1997, and 65,230 of those were born in 1 of the 50 largest cities. The relatively high rate of low-birthweight babies in big cities raises a number of troubling issues. Research shows that women who do not receive adequate early prenatal care are more likely to give birth to a low-birthweight baby and that mothers who lack health insurance are less likely to seek and obtain prenatal care. According to Census Bureau data for 1998,¹⁵ more than one-third (35 per-

cent) of mothers who smoked during pregnancy may be symptomatic of other conditions that reflect an unhealthy approach to pregnancy and childbearing. Data on smoking during pregnancy on birth certificates in California, New York (except for New York City), Indiana, and South Dakota were not compatible with NCHS standards. Therefore, these data are missing for some cities, and the figure shown under the Top 50-City Average reflects only the 41 cities where these data were collected.

While nationally, 13.2 percent of total births were to mothers who smoked during pregnancy, the average was only 11.2 percent in the largest cities (see Table 1). To some extent these data may reflect the concentration of blacks and Hispanics in large cities. In 1997, only 10 percent of black mothers and 4 percent of Hispanic mothers smoked during pregnancy, compared to 17 percent of Non-Hispanic whites.¹⁶ Among

BEST COPY AVAILABLE

cent) of all Latinos and more than one-fifth (22 percent) of all African Americans did not have health insurance. People living in poverty, high school dropouts, and young adults (ages 18 to 24) are among the groups least likely to have health insurance. Among women of childbearing age (15 to 44), 25 percent of those living in central cities lacked health insurance, compared to 17 percent of those living in the suburbs. Among Hispanic women of childbearing age living in central cities, 43 percent lacked health insurance.

Nationwide, 11.4 percent of births in 1997 were preterm births, compared with an average of 12.6 percent in the 50 largest cities (see Table 1). San Francisco and San Jose had the lowest percent of births that were preterm in 1997 at 9.0 percent, while Baltimore and the District of Columbia had the highest rate at 18.3 percent. Nationally, the share of babies who were preterm increased by 8 percent between 1990 and 1997 (see Table 2).

INDICES

In addition to presenting eight individual indicators, we combined some measures to reflect two critical dimensions regarding a birth. One index reflects the health status of a baby, and the other index reflects a set of risks based on social characteristics of the mother. Combining several measures into an index provides a more comprehensive picture of well-being.

Four indicators that reflect some dimension of health can be put together to form a Healthy Birth Index. The four indicators are birthweight, 5-minute APGAR score, gestation period, and start of prenatal care. More details about this index are provided in the Definitions and Data Sources section.

PERCENT PRETERM BABIES (LESS THAN 37 COMPLETED WEEKS OF GESTATION)
Babies born preterm often suffer related health and development problems such as low birthweight. A shortened gestation period is also related to an increased risk of infant death (death in the first year of life).¹⁸

While 7.5 percent of all births in the country in 1997 were lowweight births, the average was 8.8 percent in the 50 largest cities (see Table 1). In 1997, San Jose had the lowest rate of low-birthweight babies at 5.8 percent, and Baltimore had the highest rate at 14.1 percent. During the 1990s, the share of babies born weighing less than 5.5 pounds has been rising. The share of births that are low-weight babies has increased from 7.0 percent of all births in 1990 to 7.5 percent in 1997 (see Table 2).

MAKING CONNECTIONS CITIES

Making Connections is the centerpiece of the Annie E. Casey Foundation's multi-faceted effort (called Neighborhood Transformation/Family Development) to improve the life chances of vulnerable children by helping to strengthen their families and neighborhoods. *Making Connections* has launched a three-year demonstration phase in which we are working with neighborhoods in 22 cities to promote programs, activities, and policies that contribute to strong families.

The primary aim of this effort is to stimulate and support a local movement that engages residents, civic groups, political leaders, grassroots groups, public and private sector leadership, and faith-based organizations in an effort to help transform tough neighborhoods into family-supportive environments. *Making Connections* is about strengthening families by connecting them to the opportunities, resources, and support they need to raise healthy, con-

fident, and successful children. The three kinds of connections we have identified as most critical include economic opportunity, social networks, and services and supports. *Making Connections* seeks to foster and deepen these connections in selected neighborhoods in these 22 cities. We are working with neighborhoods to identify relevant indicators and interim benchmarks that can be used to gauge progress in improving conditions for families. This effort seeks to draw from, build on, and weave together what our work, the work of others, and the experience of communities show to be the most effective practices and strategies in community building, system reform, family support, and economic development.

On the Risk Index Based on Maternal Characteristics, 6.6 percent of births nationwide in 1997 occurred to unmarried, teenage, high school dropouts, while the average for the 50 largest cities was substantially higher at 8.6 percent (see Table 1). Among the 50 cities, the rate ranged from a low of 2.6 percent in Seattle, to a high of 14.9 percent in Milwaukee and Baltimore.

	City	1997 Population	1997 Number of Births
	Atlanta	402,590	8,407
	Baltimore	657,545	9,767

Appendix 1 provides a ranking of the 50 largest cities on each of the indicators used in this *KIDS COUNT Special Report*. Data for the 5 *Making Connections* cities are included at the end of each table, but they are not included in the rankings. For most of the measures, the highest/best rank is one (1) and the lowest/worst rank is fifty (50). For two measures (Percent of Total Births to Mothers Who Smoked During Pregnancy and Healthy Birth Index), data were not available for every city. Therefore, the lowest/worst rank may be lower than 50. Whenever there is a tie between two or more cities, each city is assigned the higher/better rank.

Percent of total births to unmarried women

Percent of total births to mothers with less than 12 years of education

Appendix 2 provides a ranking of the states and the District of Columbia on each of the indicators used in this *KIDS COUNT Special Report*. For most of the measures, the highest/best rank is one (1) and the lowest/worst rank is fifty-one (51). For two measures (Percent of Total Births to Mothers Who Smoked During Pregnancy and Healthy Birth Index) data were not available for every state. Therefore, the lowest/worst rank on these indicators is lower than 51. Whenever there is a tie between two or more states, each state is assigned the higher/better rank. These rankings include data for states even if there were no cities in the top 50 in that state.

*N.A.=Not Available.

*Not all states are included in this figure.

Healthy Birth Index: 1997 is the percentage of births classified as healthy because they met all of the criteria listed below. This indicator could not be constructed for cities in California and Texas because these states do not report the 5-minute APGAR score, one of the components of this index. The factors are as follows:

1. Birthweight of at least 5.5 pounds.

2. 5-minute APGAR score of 9 or 10. APGAR scores are a commonly used global measure to gauge the health of newborns. The letters in APGAR represent the following: A=appearance, P=pulse, G=grimace (reflex), A=activity, and R=respirations. Zero, 1, or 2 points are assigned to each dimension when the assessment is performed. The score is collected at 1 and 5 minutes of life for the infant, crucial periods for a newborn.

3. Gestation of at least 37 completed weeks.

4. Start of prenatal care in first trimester.

SOURCES: City data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. State data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Number of Births by Maternal Characteristics: 1997 contains information about age, marital status, educational attainment, and race/Hispanic origin of the mother. Detailed information about the first three items above is presented elsewhere in the Definitions and Data Sources section. Therefore, we will focus on race/Hispanic origin here.

On birth certificates, as on most federal data collection forms, the question regarding whether a person is Hispanic is separate from the question asking whether a person is white, black, Asian or Pacific Islander, or Native American. Consequently, people who indicate that they are Hispanic must also select a racial group. A birth to a woman who reported that she was Hispanic and white would be included in figures for both of these groups. In order to create mutually exclusive categories, Hispanics were removed from the black and white racial categories in the tabulations presented here. This allows more meaningful comparisons between minorities and the group people typically think of when we say "white."

It should also be noted that these figures represent the race of the mother, not the race of the child. This is important because increasing numbers of children are born to parents of different races.

SOURCES: City data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. State data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Percent Low-Birthweight Babies (less than 5.5 pounds) is the percentage of live births weighing less than 2,500 grams (5.5 pounds). The data are reported by the mother's place of residence, not the place of birth. Births of unknown weight were not included in these calculations.

SOURCES: City data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. State data: Ventura, S.J., J.A. Martin, S.C. Curtin, and T.J. Mathews, 1999, "Births: Final Data for 1997," *National Vital Statistics Reports*, Vol. 47, No. 18, Table 46, National Center for Health Statistics, Hyattsville, MD.

Percent of Teen Births to Women Who Were Already Mothers is the percentage of births that were second or higher order births to mothers who were between the ages of 15 and 19 at the time of the birth. This measure is often referred to as "Repeat Teen Births." The data are reported by the mother's place of residence, not the place of birth. Birth certificates that did not contain information on birth order were not included in this calculation.

SOURCES: City data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. State data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Percent of Total Births to Mothers Receiving Late or No Prenatal Care is the percentage of births that occurred to mothers who reported receiving prenatal care only in the third trimester of their pregnancy, or receiving no prenatal care. Birth certificates that did not report information about prenatal care were not included in this calculation.

SOURCES: City data: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. State data: Ventura, S.J., J.A. Martin, S.C. Curtin,

and T.J. Mathews, 1999, "Births: Final Data for 1997," *National Vital Statistics Reports*, Vol. 47, No. 18, Table 34, National Center for Health Statistics, Hyattsville, MD.

Percent of Total Births to Mothers Who Smoked During Pregnancy is the percentage of women who smoked during pregnancy. The data are reported by the mother's place of residence, not the place of birth. In 1997, data for smoking were not collected in California, New York (except New York City), Indiana, and South Dakota. Birth certificates on which information on smoking during pregnancy was not reported were not included in this calculation.

SOURCES: **City data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. **State data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Percent of Total Births to Mothers With Less Than 12 Years of Education is the percentage of women who had completed fewer than 12 years of education at the time of the birth. The data are reported by the mother's place of residence, not the place of birth.

Birth certificates on which maternal education was not reported were not included in this calculation.

SOURCES: **City data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. **State data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Percent of Total Births to Women Under Age 20 was calculated by dividing the number of births to women under age 20 by the total number of births to women of all ages. The data are reported by the mother's place of residence, not the place of birth. It should be noted that this is not the same as a teen birth rate and that this percentage is also affected by the fertility of women over age 20.

SOURCES: **City data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. **State data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Percent Preterm Babies (less than 37 completed weeks of gestation) is the percentage of babies born with a gestational age of less than 37 completed weeks. The data are reported by the mother's place of residence, not the place of birth. Birth certificates that did not report gestational age were not included in this calculation.

SOURCES: **City data:** National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999. **State data:** Ventura, S.J., J.A. Martin, S.C. Curtin, and T.J. Mathews, 1999, "Births: Final Data for 1997," *National Vital Statistics Reports*, Vol. 47, No. 18, Table 19, National Center for Health Statistics, Hyattsville, MD. **Special tabulation by Division of Vital Statistics, 1999.**

Risk Index Based on Maternal Characteristics: 1997 is the percentage of births classified as high risk because the mother met all of the criteria listed below.

1. Under age 20, and
2. Unmarried, and
3. Had less than 12 years of education.

California, New York (except New York City), Indiana, and South Dakota.

Total births in city is the total number of births in a given city for 1997.

SOURCE: National Center for Health Statistics, special tabulation by Division of Vital Statistics, 1999.

Total population of city is the 1997 Census Bureau estimate of the total population of each city.

SOURCE: U.S. Bureau of the Census (online) available at <http://www.census.gov/popluation/estimates/metro-city/scts> (October 22, 1999).

Top 50-City Average is the unweighted mean of the data for each of the 50 largest cities based on Census Bureau population estimates for 1997. In other words, this figure is the average of the figures for each of the 50 cities without taking into consideration the size of each city. For the Healthy Birth Index and the Percent of Total Births to Mothers Who Smoked During Pregnancy, the average is based only on those cities or states with reported data. For the Healthy Birth Index, data for cities in the following states were unavailable: California and Texas. For the Percent of Total Births to Mothers Who Smoked During Pregnancy, data were unavailable for cities in the following states:

Primarily Contacts for State KIDS COUNT Projects

The Annie E. Casey Foundation is a private charitable organization dedicated to helping build better futures for disadvantaged children in the United States. It was established in 1948 by Jim Casey, one of the founders of United Parcel Service, and his siblings, who named the Foundation in honor of their mother. The primary mission of the Foundation is to foster public policies, human-service reforms, and community supports that more effectively meet the needs of today's vulnerable children and families. In pursuit of this goal, the Foundation makes grants that help states, cities, and communities fashion more innovative, cost-effective responses to these needs.
